HEAT - AN INTERNAL VIEW

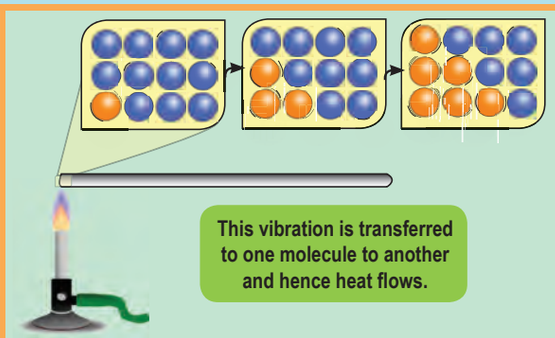

Substances are made up of molecules. The molecules in any object are in a state of vibration or movement. This cannot be seen with our naked eyes

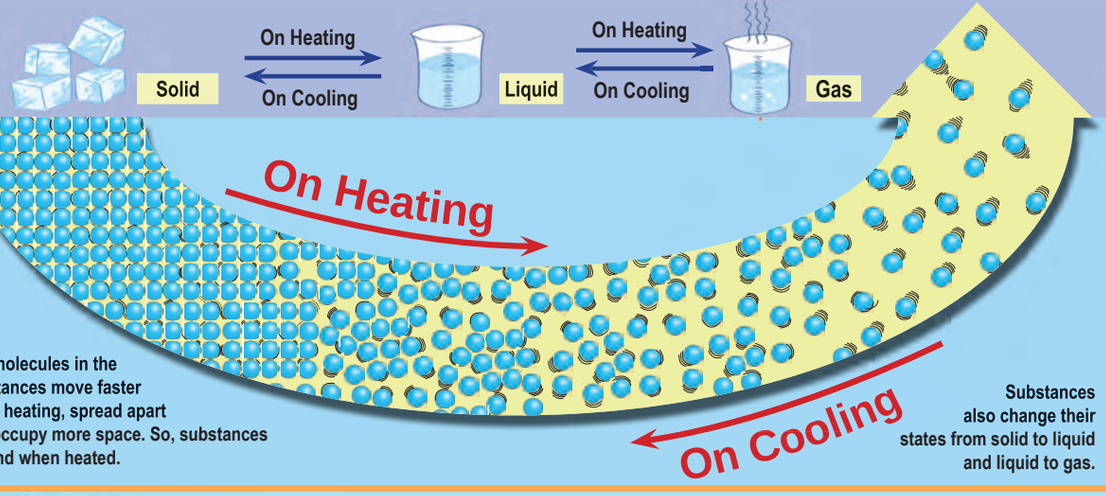

When substances are heated the vibration and movement are increasing

The total number of molecules remain unchanging after heating. Hence, No Change in weight.

This vibration is transferred to one molecule to another and hence heat flows.

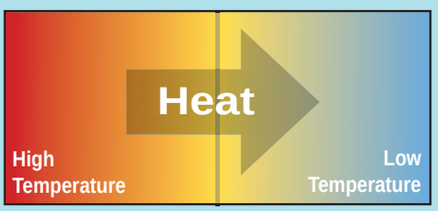

The molecules in the substances move faster when heating, spread apart and occupy more space. So, substances expand when heated.

Substances also change their states from solid to liquid and liquid to gas.

Water 'flows' when there is a difference in the 'levels' of water in different places. The 'temperature' of an object is like the water level – it determines the direction in which 'heat' will flow.
